Coma, Hyperthermia, and Bleeding
Associated with Massive LSD Overdose*,†:
A Report of Eight Cases

Although there have been many reports of overdose with D-lysergic acid diethylamide (LSD) in humans, little toxicologic data are available. The physiologic effects of LSD in doses greater than 1 mg have not been studied in humans and the lethal dose must be

interpolated from animal studies. We performed extensive toxicologic studies on eight people who took large doses of LSD; the results and clinical-toxicologic correlations are reported herein.

REPORTS OF CASES

On July 29, 1972, four women and four men ranging in age from 19 to 39 years were admitted to the emergency room at San Francisco General Hospital for drug overdose. Following a dinner party, they had "snorted" (inhaled through a straw placed in one nostril) a small amount of cocaine and a quantity of white powder believed to be cocaine. All eight were reported to have snorted at least two "lines" (rows of powder measuring approximately 3 x 4 x 30 mm) of the second substance. Within 5 min they experienced anxiety, restlessness, generalized paraesthesias and muscle discomfort, vomiting, and physical collapse. Ten minutes later they were admitted to the emergency room in varying degrees of intoxication (Table 1 and Appendix).

Five were comatose when first seen and most were extremely hyperactive with severe visual and auditory hallucinations at some point during their course. Three required endotracheal intubation and assisted ventilation and three aspirated vomitus. All had sinus tachycardia, widely dilated and fixed pupils, emesis, flushing, and sweating. Fever developed in four and diarrhea in two. Transient hypertension was present in three patients and no patient had convulsions. All had coagulopathy as manifested by the inability to form firm clots and absence of clot retraction in the blood specimen tubes. Seven had guaiac-positive vomitus and four showed evidence of mild generalized bleeding (microscopic hematuria in two, gross hematuria in two, oozing at venipuncture sites in three and small amounts of blood in the vomitus or stool in four patients).

Laboratory data showed normal or negative values (see Appendix) for the following: blood glucose and serum sodium, potassium, and bicarbonate levels, hemoglobin (13.0 to 16.4 gm/dl), platelet count (186,000 to 458,000/µl), prothrombin time (11.0 to 12.5 sec) and partial thromboplastin time (19.3 to 38.7 sec), chest roentgenograms, and electrocardiograms. Results of liver and renal function tests were within normal limits in the three patients studied. Direct examination of the blood clots and results of clot retraction tests on several patients showed friable clots that fell apart easily without dissection, and absence of clot retraction (Fig. 1). Supportive care included respiratory assistance, use of hypothermic blankets, and administration of antibiotics and corticosteroids when indicated. Bleeding was mild and disappeared within 4 to 6 hr. Blood transfusions were

unnecessary and all patients recovered completely within 12 hr. All were discharged or left the hospital within 48 hr of admission. No residua were observed in a year of direct follow-up of five patients.

TOXICOLOGIC DATA

Specimens of blood, urine, and gastric contents were obtained on admission from seven patients and analyses were performed as follows.

Gastric Content

Extraction of the gastric contents for toxicologic screening was performed according to the method of Sunshine [1] and analyzed by thin layer chromatography according to a modified method of Mule
MASSIVE LSD OVERDOSES

[2]. All basic gastric content extracts showed the presence of an ergot alkaloid. By the photo-degradation method of Anderson [3] and using a combination of eight reference substances,* this substance was further characterized as D-lysergic acid diethylamide. The results, shown in Table 2, were confirmed by mass spectroscopy.† The mass peaks of the isolated material corresponded with those reported in the literature and those of authenticated LSD-25, which was used as a control sample.

Urine

Preliminary screening by Mulé's [2] method of thin layer chromatography showed possible traces of cocaine in some specimens. Therefore, specimens were rechecked by homogeneous enzyme immunoassay [4] for benzylecgonine, the main cocaine metabolite in urine [5]. Two of the urine specimens contained small amounts of benzylecgonine (Table 2).

Blood

Blood was analyzed for LSD by the back extraction method of Aghajanian and Bing [6] and the results were compared with standards of serum containing 5, 10, 20, and 40 ng LSD/ml. All specimens analyzed contained LSD (Table 2). Blood was analyzed for cocaine, using the same general method as for urine, and for ethanol and other volatile substances, using gas chromatography [7]. No specimen contained cocaine and two specimens contained small amounts of ethanol (Table 2).

CONFISCATED MATERIAL

A white flaky material (208 mg) was confiscated by police and identified as the large quantity of powder used at the party. Analysis by thin layer chromatography, fluorescent analysis, mass spectrography, and the melting point and mix melting point identified this substance as almost pure (80 to 90%) D-lysergic acid diethylamide tartrate.

DISCUSSION

Intranasal administration of crushed LSD tablets is a common method of administration by LSD users when a rapid onset of action is desired. The active use of this route by our patients was corroborated by the onset of symptoms soon after administration of the white powder, the absence of LSD in screening samples of food and wine from the party and the absence of symptoms in members of the party who did not use the powder. The lethal dose of LSD for humans
is not known, but it ranges from 46 mg/kg in mice [8] to 0.3 mg/kg in rabbits [8] to 0.1 mg/kg in Asiatic elephants [9]. Interpolated for the body weight of humans, this would result in a lethal dose of 0.2 mg/kg or an approximate lethal dose of 14,000 µg [8]. The toxicologic data and the purity of the powder used by our patients indicate that milligram amounts of the drug were administered, placing the patients at risk of having severe and possibly lethal reactions.

LSD is capable of many and varied physiologic, psychologic, and biochemical effects [8, 10, 11]. Most of these effects are thought to be due to LSD's ability to affect 5-hydroxytryptamine receptors both centrally and peripherally [12-14] and to its generalized stimulation of the reticulocortical system [8]. The previously observed physiologic manifestations of psychosis, hyperexcitability, tachycardia, mydriasis [8, 15, 16], and hyperthermia [17] were prominent in our patients, but the degree of central nervous system depression and respiratory inhibition that occurred in these patients has only been demonstrated in animals given very large doses [8]. Furthermore, the generalized bleeding problem observed in four of our patients has not been described before with LSD. The clinical and laboratory data suggest that platelet function was abnormal. Little literature on LSD and platelet function is available. However, Michal [18] showed that LSD-25 in 1 to 3 nM concentrations could significantly inhibit 5-hydroxytryptamine-induced platelet aggregation in vitro; no effect on adenosine diphosphate-induced aggregation was noted. Cocaine also affects platelet function in vitro in much larger concentration [19, 20]. Our analytical data do not indicate that cocaine played a significant role in these cases, making the possibility of cocaine-induced platelet dysfunction unlikely. However, more evidence is needed before LSD can be implicated as the cause of the bleeding in these patients.

Treatment of our patients was entirely supportive and recovery was relatively rapid. Some of them were able to converse after 4 to 5 hr and all were normal within 12 hr. Most did not remember being brought to the hospital; otherwise, no apparent psychologic or physical ill effects were noted in a year of follow-up examinations of five patients. Most of the patients continue to use LSD intermittently. Death from LSD overdose still has not been confirmed toxicologically; nevertheless, the rapid administration of large doses of LSD in humans is associated with striking and distinctive clinical manifestations and is life-threatening.
Patient 1

A 20-year-old woman was comatose and unresponsive to pain with vomitus in the mouth and hypopharynx on arrival at San Francisco General Hospital. Breathing was shallow, irregular, and ineffective; the pupils were dilated and unreactive. There were hyperactive bowel sounds, but no diarrhea. Bleeding at venipuncture sites persisted for more than 20 min. The hemoglobin was 13.9 gm/dl, packed cell volume 43.2%, platelets 245,000/µl, and white blood cell count 19,000/µl with 35% segmented neutrophils, 2% eosinophils, 1% basophils, and 62% lymphocytes. On urinalysis there was a 2 plus reaction for blood. The blood urea nitrogen was 9 mg and creatinine 0.7 mg/dl, serum sodium was 140 meq, potassium 4.4 meq, chloride 108 meq, and bicarbonate 25 meq/liter, glucose was 115 mg/dl, prothrombin time 12.4 sec, and partial thromboplastin time 24.5 sec. Both the stool and vomitus were 3 plus reactive for blood.

The patient was supported by artificial ventilation via endotracheal tube and was placed on a hypothermic blanket and given intravenous fluids. She remained comatose and continued to bleed at the site of insertion of the endotracheal tube and in the urine. After 5 hr, the fever, coma and bleeding gradually resolved. The patient was fully awake by the 12th hour, was able to walk after removal of the tube and was discharged on the second hospital day.

Patient 2

A 19-year-old woman arrived at the hospital in an extremely lethargic state, responding only to very painful stimuli. Within 10 min she became severely agitated, spontaneously flailing her arms and legs and continuously screaming. The pupils were dilated and unresponsive to light. There was no nuchal rigidity. The bowel sounds were hyperactive, stools were formed and greenish, and the nasogastric aspirate contained small amounts of blood mixed with food. Blood oozed from venipuncture sites and large bruises formed at sites of trauma. Hemoglobin was 14 gm/dl, packed cell volume 40.8%, platelets 186,000/µl, and leukocytes 21,500/µl with 80% neutrophils, 19% lymphocytes and 1% monocytes. Prothrombin time was 12.5 sec, partial thromboplastin time 27.3 sec. Glucose was 180 mg, creatinine 1.5 mg, and blood urea nitrogen 20 mg/dl. Serum sodium was 142 meq, potassium 4.0 meq, chloride 110 meq,
and bicarbonate 25 meq/liter. There was a 4 plus reaction for blood in the urine, and the stool guaiac test reaction was 2 plus. An electrocardiogram showed sinus tachycardia.

Diazepam, 10 mg, was administered intravenously and the patient was packed in ice bags. She began to have many watery greenish stools. She was placed in a quiet dark room and became quieter. Over the next hour she became gradually less responsive and finally only responded to deep pain. The arterial blood $pO_2$ was 56 mm Hg, $pCO_2$ 46 mm Hg, and $pH$ 7.28. Respiratory arrest necessitated intubation and respiratory assistance for 4 hr at which time she began to regain consciousness. Within the next 6 hr the patient recovered fully and was discharged the following day.

**Patient 3**

A 28-year-old woman arrived at the hospital vomiting and unable to speak, had an expressionless stare and was unresponsive even to severe pain. The pupils were dilated and fixed and the reflexes were hyperactive. She did not have diarrhea. The hemoglobin was 14.5 gm/dl, packed cell volume 41.2% and leukocytes 23,200/µl with 67% neutrophils, 1% basophils, 36% lymphocytes, and 6% monocytes. The platelets were normal on a blood smear. The prothrombin time was 11.9 sec, partial thromboplastin time 38.7 sec, and blood glucose 105 mg/dl. The vomitus was positive for blood.

Dextrose and saline solution were administered intravenously. The patient gradually became more responsive. Except for three episodes of brown watery diarrhea and transient writhing dystonic movements, the course of recovery was uneventful. The patient was completely normal after 12 hours and was discharged on the second hospital day.

**Patient 4**

A 33-year-old woman arrived at the hospital unconscious and unresponsive to painful stimuli. She had frothy sputum and vomitus in the mouth, nose, and hypopharynx. The vomitus contained small flecks of blood. The pupils were dilated and unresponsive to light. The bowel sounds were hyperactive, but there was no diarrhea. The hemoglobin was 13.0 gm/dl, packed cell volume 38.8% and white blood cell count 22,300/µl with a normal differential. Urinalysis showed a 4 plus reaction for glucose and blood. Blood glucose was 204 mg, creatinine 0.7 mg, and urea nitrogen 11 mg/dl. Serum
sodium was 141 meq, potassium 3.7 meq, chloride 103 meq, and bicarbonate 28 meq/liter. The plasma prothrombin time was 11.6 sec and partial thromboplastin time 19.3 sec. The platelets were normal on a blood smear.

The patient vomited in the emergency room, aspirated vomitus, and became apneic. Endotracheal intubation and artificial ventilation were instituted and hydrocortisone, 500 mg, and penicillin, 6 million units, were administered intravenously. Blood ooze at venipuncture sites and at the site of insertion of the endotracheal tube. Artificial ventilation was maintained for 2 hr and then terminated when the patient began thrashing about. Bleeding continued for several hours and the tube was removed approximately 8 hr after insertion. She made an uneventful recovery and left the hospital on the third hospital day.

**Patient 5**

A 39-year-old man arrived at the hospital unconscious and unresponsive to pain. He had no gag reflex while vomitus was being suctioned from his mouth and hypopharynx. He was diaphoretic with widely dilated pupils and hyperactive bowel sounds but there was no hemorrhage or diarrhea. The hemoglobin was 15.7 gm/dl, packed cell volume 46%, platelet count 294,000/µl, and leukocytes 17,500/µl with 39% neutrophils, 54% lymphocytes, 1% eosinophils, and 6% monocytes. Blood urea nitrogen was 22 mg and creatinine 1.4 mg/dl. Serum sodium was 141 meq, potassium 3.5 meq, chloride 109 meq, and bicarbonate 20 meq/liter. Arterial blood pO₂ was 52 mm Hg, pCO₂ 46 mm Hg, and pH 7.25. Urinalysis showed a 1 plus reaction for ketones and a 3 plus reaction for blood. The vomitus was positive for blood.

After 30 min it was easier to arouse the patient from coma. He was increasingly psychotic and had severe visual hallucinations. However, during the next 4 hr he became sleepy and less agitated. He gradually recovered and left the hospital against medical advice 12 hr after admission.

**Patient 6**

A 29-year-old man was unresponsive on arrival at the hospital. Except for blood pressure of 230/130 mm Hg, dilated pupils and diaphoresis, the results of physical examination were within normal limits. There was no evidence of bleeding. The hemoglobin was 16.4 gm/dl, packed cell volume 46.7 vols %, and leukocytes
17,900/μl with a normal differential count. The platelets were normal on smear and the prothrombin time was 12.5 sec. Blood glucose was 142 mg, blood urea nitrogen 19 mg, and creatinine 0.8 mg/dl. Arterial pO₂ was 104 mm Hg, pCO₂ was 28 mm of Hg, and pH was 7.41. The vomitus was positive for blood.

After 40 min the patient had gradually become more responsive though he was grossly psychotic, screamed loudly and had severe visual hallucinations. The blood pressure gradually fell to 170/110 mm Hg over an hour and was 130/70 3 hr after admission. The patient recovered without complication over the next 8 hr and left the hospital the following day.

**Patient 7**

A 28-year-old man walked into the emergency room stating that he thought he had been poisoned. He was belligerent and was having visual hallucinations. Physical examination showed no abnormalities with no evidence of diarrhea or bleeding; however, he subsequently vomited material containing blood. The hemoglobin was 16.3 gm/dl, packed cell volume 47.2% and white blood cell count 13,500/μl with 66% neutrophils, 3% basophils, 21% lymphocytes, and 10% monocytes. The platelet count was 458,000/μl, the prothrombin time was 11.0 sec, and partial thromboplastin time 34.6 sec. Serum sodium was 140 meq, potassium 4.3 meq, chloride 101 meq, bicarbonate 24 meq, and creatinine 1.4 meq/liter. Protein was 7.6 gm, albumin 4.6 gm, and bilirubin 0.3 mg/dl. Lactic dehydrogenase was 116 IU/liter, glutamic oxaloacetic transaminase 32 IU/liter, creatine phosphokinase 180 IU/liter, glucose 120 mg/dl, and alkaline phosphatase 47 IU/liter. The patient refused admission to the hospital and left after 5 hr in the emergency room.

**Patient 8**

A 28-year-old man walked into the hospital complaining of being severely frightened and of having visual hallucinations and "nightmares." Physical examination revealed no abnormalities except for diaphoresis and dilated pupils unresponsive to light. The hemoglobin was 16 gm/dl, packed cell volume 48 vols %, and white blood cell count 23,200/μl with 86% neutrophils, 11% lymphocytes, and 3% monocytes. The prothrombin time was 10.0 sec and partial thromboplastin time 22.4 sec. Platelet count was within normal limits. There was a 3 plus reaction for blood in the urine and a
1 plus reaction for protein. The patient remained in the emergency room for several hours, said he felt better and was discharged.

**SUMMARY**

Eight patients were seen within 15 min of intranasal self-administration of large amounts of pure D-lysergic acid diethylamide (LSD) tartrate powder. Emesis and collapse occurred along with signs of sympathetic overactivity, hyperthermia, coma, and respiratory arrest. Mild generalized bleeding occurred in several patients and evidence of platelet dysfunction was present in all. Serum and gastric concentrations of LSD tartrate ranged from 2.1 to 26 ng/ml and 1000 to 7000 ng/100 ml, respectively. With supportive care, all patients recovered. Massive LSD overdose in humans is life-threatening and produces striking and distinctive manifestations.
